Children with Autism and Related Disorders

Autism is a disorder that effect 20,000 children in years.

Children born to older parent have risk to have autistic, genetic, low birth weight. Many children with autism have a problem with communication patterns of behavior, repeating same behavior. Autistic child might have difficulty to express their felling to others. Some ASD kids have negative social experiences, reporting feelings of loneliness, social exclusion, and bullying.

There are different ways to find if the child has autism. When they are nine months and the child don't respond normally, the child has some sort of disability. Speech delay and learning interest in limited things, filing shy does not open with everything they see in from of them. Some children also would not explain how they fell or what they want. Sometimes they don't want to talk to anyone. For example, they

like to play by themselves. Children with autism are also very possessive about one thing, that they do not want to share with others.

Some children seem to live in their own world. They are not very interested in what is going around them, like lack of social awareness.

Some children with autism do not like to play any types of activities when they are told. Instead, they will do what they want to do because of a behavioral problem. Their behaviors are very unpredictable, without any reason they will cry, laugh, or scream too. Children with autism sometimes like one thing but not necessarily like something the next day. The children with an autism problem can be helped by constantly helping them by giving different things. Some children need their time to open up about their feelings to the people who want to hear. Children are often seen to talk slowly or take a long time to say their words or their thoughts.

When a child has autism, a doctor can tell by when the child has speech and behavior that is different than normal children. With them everything happens all of a sudden. At the age of three a professional can talk about a child's developmental problem or not by observing them. Some

children be checked for all development delay at nine months. Children will have verbal and numerable communication.

A professional teacher knows how to help the special children with disabilities. In this course I got to learn different disabilities and how the teacher helps the children their way out. The teacher does not randomly give the children any activities to play do work on. The teacher observes the child first to help the children. I remember in one of the videos that I watched from this course the girl with autism. She was in the inclusive class and the stature strategies the teacher use is that Knowing Taysha. What she like to play with. What gets her attention. By doing that the teacher found out that Taysha was interested in music.

To help the autistic child, the teacher needs to find different ways, constantly guide de them. Give them a lot more attention, involve them with the activities makes the child happy. Play with their favorite toy, let them choose what they want to do for the day by unlimited option so that child don't get bored.
